# MD5 Specification

- › Works on 512 bit blocks of the message
- › Produces a 128 bit hash code

# Message Preparation

## › **Padding**

The Message is padded to an exact multiple of 512-bit blocks

1 is appended to message

The remainder (less 64 bits) is filled with as many 0's as required

The last 64 bits are used to represent the message length

## › **Block subdivision**

Subdivided to a number of 512-bit blocks

# Basic Idea

- › Start from a constant 128-bit state
- › Divided into four 32-bit words, denoted as A, B, C, and D
- › Each 512-bit block will be divided to 16 32-bit block
- › Each 32-bit block will be used to modify this 128-bit state for 16 times
- › Every 16 operations are called *one round*
- › 4 rounds, with slightly different operations

# Some constants

$M_j$  is the  $j^{\text{th}}$  sub-block of the message block.

For step  $i$ :

$t_i = 2^{32} * \text{abs}(\sin(i))$  where  $i$  is measured in radians.

$s$  is the number of bits to be shifted:
